Methodology Notes

Distribution fitting

Truncated normal (support [0,100]) fitted via MLE on pooled band counts.

6 bins: ≥ 70 , 60–69, 50–59, 40–49, 30–39, < 30 .

81 papers fitted (65 band MLE, 16 moment estimates). 2020 excluded.

Goodness of fit: chi-squared test (bins merged where expected < 5).

Classification rules

1st: $\text{avg} \geq 68.5$, ≥ 2 marks of 70+, no mark < 50 .

2.1: $\text{avg} \geq 59.0$, ≥ 3 marks of 60+.

2.2: $\text{avg} \geq 49.0$, ≥ 3 marks of 50+.

3rd: $\text{avg} \geq 40.0$, ≥ 3 marks of 40+.

Monte Carlo simulation

$\text{mark}_i = \mu_i + \theta + \varepsilon_i$, $\theta \sim N(0, \sigma^2_{\text{ability}})$, $\varepsilon_i \sim N(0, \sigma^2_{\text{paper}} - \sigma^2_{\text{ability}})$.

$\sigma_{\text{ability}} = 2.74$, calibrated to 23.4% first-class rate.

100,000 simulations per paper combination.

Temporal trends

OLS regression of mean mark on year, excluding 2020.

95% CI: $\text{slope} \pm t_{\{n-2, 0.025\}} \times \text{stderr}$.

Key limitations

- Truncated normal may poorly fit papers with ceiling effects or bimodality.
- Single-factor ability model; same-subject papers may be more correlated.
- Selection effects: observed distributions reflect who chose the paper.
- Temporal pooling: distributions are averages across years, not year-specific.
